Updated on 7 July at 16:20.

The corona virus epidemic has calmed down in Finland. From now on, the THL will only update the situational review page on business days, but will continue to monitor the situation closely at the same time. Hospital districts report deaths associated with the disease and the number of patients in hospital and intensive care three times a week on Mondays, Wednesdays and Fridays. The corona map will continue to be updated on a daily basis.

## The situation in Finland in brief

- Reported cases in total: **7,262** (+5\*)
- Tested samples in total: approximately **261,400** (+5,900\*)  
\* Change from previous day. The overall change to the number of cases is five cases. All of these are old cases that have been reported retrospectively, not recent cases reported during the previous two weeks. Also see below for information on [Reporting of data](#).
- A total of **329\*\*** deaths associated with the disease have been reported.
- The number of patients in hospital care in Finland is **19\*\***
- The number of patients in intensive care in Finland is **1\*\***  
\*\*The figures were last updated on Mon 6 July. The reported patients in hospital care have been confirmed to have a coronavirus infection with laboratory testing. However, the patient's need for hospital treatment may be related to medical reasons other than the symptoms caused by coronavirus.

According to the data in the National Infectious Diseases Register, the average age of persons infected with corona has decreased during the epidemic (in April, 45 years of age; in May, 41 years of age; in June, 39 years of age). In June, cases have been diagnosed especially in young people and working-age people. Differences have also been observed between the genders, In June, twice as many men aged 20-29 were diagnosed with infections as women of the same age. The increase in the share of working age men may be partly explained by the clusters of coronavirus found at construction sites. The decrease in the average age of infected persons can also be explained by the fact that fewer clusters linked to elderly care units have been observed than before.

- In relation to Finland's total population (5,543,233), the prevalence of cases is **131** cases per 100,000 people.
- During the most recent seven-day monitoring period (28 June–4 July), 46 new cases were diagnosed. The incidence of new cases in relation to the population was 0.8 cases per 100,000 inhabitants. During the previous monitoring period (21-27 June), the corresponding figures were 63 new cases with an incidence of 1.1 cases per 100,000 inhabitants.
  - Reporting delays can affect the numbers stated for the most recent monitoring period. It is therefore not possible to draw any certain conclusions on the increase or decrease of cases on the basis of the most recent monitoring period.
- Virus testing currently has a capacity of over **13,000** tests per day.
- An estimated 6,700 people have recovered, which is around 90% of reported cases. The estimate is based on the follow-up of the observed cases over a period of three weeks (21 days). A person is considered to have recovered, when they do not have any follow-up data related to the progress of the illness after 3 weeks have passed from diagnosis. The estimate is updated once a week on Wednesdays, the estimate has been updated on 1 July.
